Category:Windows-only freeware Category:Image organizersThe present invention relates to a method of forming a head portion and a disk drive for driving a disk to rotate. In a hard disk drive, it is necessary to reduce the head flying height to achieve higher recording density, in order to realize a high transfer rate in the recording and reproducing operation of the magnetic head and an increase in the storage capacity. In order to achieve a decrease in the head flying height, the disk drive must be provided with a mechanism for pressing the magnetic head against the disk. For example, JP-A-5-275357 and JP-A-7-94765 propose a flying head device including a mounting member for mounting a head slider having a magnetic head formed thereon, a pressurizing mechanism for pressing the head slider against the disk, and a spring member for elastically pressing the mounting member in the radial direction of the disk. JP-A-5-275357 and JP-A-7-94765 propose a flying head device which includes a floating slider having a magnetic head formed thereon, a pressurizing mechanism for pressing the slider against the disk, and a loading member disposed at the end of the slider for pressing the slider against the disk. The floating slider is mounted on a mounting member by a fixation screw. The fixation screw is turned to press the slider against the disk. The pressurizing mechanism is disposed between the loading member and the mounting member. The mounting member, the floating slider, the fixation screw, and the pressurizing mechanism are disposed in a housing of the disk drive. The disk drive comprises a spindle motor for rotating the disk and a head actuator for moving the floating slider along the radial direction of the disk. The housing is formed by a pair of frames which are integrally molded by resin. The
