Intermittent regimens of topotecan, cisplatin, and vinorelbine versus topotecan and cisplatin: an Eastern Cooperative Oncology Group phase 3 study (E1186). We evaluated the activity and toxicities of an intermittent regimen of 3 consecutive weekly cycles of topotecan, cisplatin, and vinorelbine (TPV) compared to an identical schedule of a single, nonintermittent cycle of topotecan and cisplatin (TP). Eligible patients had stage IIB or III nonmetastatic breast cancer with a baseline Eastern Cooperative Oncology Group performance status of 0 or 1, a left ventricular ejection fraction of 50% or greater, and adequate organ function. After a 3-week washout, patients were treated every 3 weeks with TPV (cisplatin, 45 mg/m², on day 1; topotecan, 1.25 mg/m², on days 1 to 3; and vinorelbine, 25 mg/m², on days 1 and 4) for 2 cycles followed by 6 cycles of TP (cisplatin, 45 mg/m², on day 1) for all patients. The primary end point was the percentage of response. One hundred sixty-five patients were enrolled; 167 eligible patients were evaluated for response and toxicity. The overall response rate was 94% (95% confidence interval, 87.1%-98.2%) for TPV and 89% (95% confidence interval, 79.5%-94.5%) for TP; the difference was not significant. The median duration of response was 24 and 21 months for TPV and TP, respectively, with median follow-up of 17 and 16 months for TPV and TP, respectively. The median survival was 28 months (95% confidence interval, 25-31 months
